ABSTRACT
Castor is one of the important non edible oilseed crops and considered as the ancient non edible oilseed crop. The crop is affected by number of diseases. Among them leaf blight caused by Alternaria alternata and leaf spot caused by Botrytis ricini reduces the seed germination and yield up to 40-60%. Present study concentrated on location and transmission of Alternaria alternata, Botrytis ricini in castor beans during 2007-2008 kharif seasons in Karnataka. A total of 130 seed samples were collected from farmers, retail shops, fields and APMC markets and were subjected to SBM method. Five seed samples showing higher incidence of seed borne fungi in SBM were selected for location and transmission of the pathogen. The results revealed that A. alternata (10-16%) and B. ricini (9-25%) in the SBM method. A. alternata ranged from 3-8% in seed coat, 0-3% in cotyledons, while 0-1% in embryonic axis. B. ricini ranged from 2-6% in seed coat, 0-2% in cotyledons, while 0-1% in embryonic axis in kharif 2007. In kharif 2008 A. alternata (13-25%) and B. ricini (17-33%) in the SBM method. A. alternata ranged from 5-12% in seed coat, 1-7% in cotyledons, while 0-2% in embryonic axis. B. ricini ranged from 3-7% in seed coat, 1-4% in cotyledons, while 0-2% in embryonic axis. The seeds tested during kharif 2007-08 season harvested seeds favors the more number of pathogens in the seed coat & cotyledons than in the other components. The transmission of A. alternata and B. ricini was 16.6% in kharif 2007. In kharif 2008, the transmission was 23.2% in all the five seed samples. The present study reveals that the disease transmission is more during kharif-2007 season than 2008. The above pathogens causes leaf spot, blight and gray mold diseases of castor.

Key words: Castor, location, Transmission, A. alternata, B. ricini.

INTRODUCTION
Castor (Ricinus communis L.) is one of the important non edible oilseed crops and considered as the ancient non edible oilseed crop. It is indigenous to eastern Africa and most probably originated in Ethiopia [19]. This crop is widely distributed throughout the tropics and sub-tropics and is well adapted to the temperate regions of the world. Castor is cultivated over an area of 2061 hectares with a production 17493 tones and productivity 193 kg/ha in Karnataka [1]. Castor plant is affected by number of fungal diseases. The important diseases are wilt-Fusarium oxysporum f.sp.ricini, leaf spot & blight-Alternaria ricini, cercospora leaf spot-Cercospora ricinella, root rot, stem rot & charcoal rot-Macrophomina phaseolina, seedling blight-Phytophthora parasitica, capsule rot-Cladosporium oxysporum, fruit rot & Gray rot-Botrytis ricini, rust-Melampsora ricini, powdery mildew-Leveillula taurica, phyllosticta leaf spot-Phyllosticta bosensis, angular leaf spot-Botrytis sp., damping off-Phytophthora aphanidermatum [10], [11]. A. alternata and B. ricini are the causal agent of leaf spot, leaf blight and gray mold diseases of castor [6], [8], [15], [18]. In the present work the occurrence, Location, seed to seedling transmission, their frequency of mortality, recovery of pathogens and its significance were studied.

MATERIALS AND METHODS

Collection of castor seed samples
A total of 130 samples were collected from castor during kharif, 2007-08. Seeds were harvested from mature castor plants, farmers, fields, retail shops and APMC markets in different agro climatic
regions of Karnataka state. The collected seed samples were dried in sunlight to bring down the safe storage seed moisture and were subjected to standard blotter method (SBM).

**Standard blotter method (ISTA.1993)**

Seed samples were analyzed for the detection of seed-borne fungi by blotter method following ISTA. 1993 with some modifications. In this method three layers of blotter paper were soaked in sterilized and placed at the bottom of the Petri plates. 100 seeds were sterilized with 0.2% sodium hypochloride solution for 2 to 3 minutes and seeds taken randomly from each sample and were placed in ten Petri plates (Ten seeds per plate). The Petri plates with seeds were then incubated at room temperature for seven days in the laboratory. The plates were alternating cycles of 12 hrs light and 12 hrs darkness for seven days. Sterile distilled water was aseptically added to each Petri plates under incubation every third day in order to keep the blotter is sufficiently moist. Germination and fungi associated with the seeds were recorded during the incubation period. Each of the incubated seeds was examined under stereo binocular microscope to ascertain the presence of fungi. Some times were not apparent even after seven days of the incubation. In such condition, the Petri plates were allowed for further incubation. A temporary slide was prepared from each colony, which could not be identified stereo binocular microscope. Fungi were identified by preparing temporary slides and examined under labomed vision 2000 microscope. In fewer cases the fungi from the incubated seeds were transferred to PDA medium in Petri plates aseptically and incubated under controlled temperature (28±1°C) for 3 to 10 days and then examined under labomed vision 2000 compound microscope. The analysis of seed-borne mycoflora was identified by using standard guides and manuals [4], [13], [14], [17].

Five seed samples showing higher incidence of *A. alternata* and *B. ricini* in Standard blotter method and were selected for location and transmission studies.

**Location of the pathogen by component plating method**

This method is adapted to know the location of the pathogen in different components of the seed [5]. The individual seed components were excised after soaking the surface sterilized seeds 0.2% sodium hypochloride (NaOCl) for three min, in sterile distilled water for five hours. The seed coat, cotyledons and embryonic axis (Plumule and radicle) were dissected aseptically using forceps and needles on blotter. Each component was dipped separately in 0.2% sodium hypochloride solution (NaOCl) for 50 to 90 seconds and was placed on SBM method. One hundred seeds were dissected in each sample and ten replication were maintained. The plates incubated at 25±2°C for room temperature. All the components plated individually. After eight day observation of these plates under stereobinacular microscope. Fungal infection in different seed components was determined based on the appearance of the fungus on the SBM and the percentage of infection was calculated.

**Disease transmission studies in the field**

Among the total seed samples, five samples shows a higher incidence of *A. alternata* and *B. ricini* were selected for disease transmission in experimental plot. The seed samples were sterilized by 2% sodium hypochloride solution (NaOCl) for 2-3 minutes and in the distilled water before sowing the seeds. Before sowing the seeds the experimental plot were prepared by 20 x 20 meter (row and columns) leveled and ploughed. Each sample selected 100 seeds in ten replicates. Sterilized seeds were directly sowing in the fields in the month of July -2007. The proper agronomical practices were followed for raising the plants. All the seeds have germinated after 7-10 days. In experimental plots, 15 plants were randomly selected by selecting five leaves randomly in each plant. The severity of the disease was assessed by using 0-9 scale [9] and percentage of diseases index was calculated by using the formula.

\[
\% \text{ of disease} = \frac{\text{Sum of individual ratings}}{\text{No. of leaves examined} \times \text{Maximum disease grade (9)}}
\]

Seed to seedling transmission of *A. alternata* and *B. ricini* of pathogens were studied.

**Recovery of pathogens from diseased plants**

Seeds were collected from experimental plots in rabi and summer seasons, subjected for seed health testing methods. Again the seeds sown in kharif 2008 season in experimental plot for recovery of pathogens were studied. These seeds yielded the *A. alternata* and *B. ricini*. The study shows that *A. alternata* and *B. ricini* are transmitted from seed to seedlings and to the seeds [16].

**RESULTS AND DISCUSSIONS**

During the field survey the leaf spot, leaf blight and gray mold of castor was noticed in all visited fields during kharif and rabi seasons in 2007-
The severity of the leaf spot, leaf blight and gray mold diseases was more in kharif-2008 then 2007.

**Location of the pathogen in different seed components**

Location of the pathogen in the seed is important to control seed borne pathogens. Based on the location of the pathogen in the seeds, the chemicals are selected to prevent the seed borne pathogens. Majority of the seed borne pathogens are lodged on the seed coat, some pathogens are in the cotyledons and some are in embryonic axis (plumule and radical). Many researchers [2], [3], [5], [12], [16] reported the location of the pathogen in seed coat, cotyledons, endosperm and embryonic axis (plumule and radical) of various oil seed crops.

In castor, *A. alternata* (10-16%) and *B. ricini* (9-25%) in the SBM method. *A. alternata* ranged from 3-8% in seed coat, 0-3% in cotyledons, while 0-1% in embryonic axis. *B. ricini* ranged from 2-6% in seed coat, 0-2% in cotyledons, while 0-1% in embryonic axis in kharif 2007. In kharif 2008, *A. alternata* (13-25%) and *B. ricini* (17-33%) in the SBM method. *A. alternata* ranged from 5-12% in seed coat, 1-7% in cotyledons, while 0-2% in embryonic axis. *B. ricini* ranged from 3-7% in seed coat, 1-4% in cotyledons, while 0-2% in embryonic axis. The seeds tested during kharif 2008 season harvested seeds favors the more number of pathogens in the seed coat & cotyledons than in the other components.

The expression of *A. alternata* and *B. ricini* was more percentage in seed coat than other seed components. The seeds were harvested during kharif-2008 season favored for the more number of pathogens in the seed coat than other components. The seeds harvested during kharif-2007 season shows a less incidence of mycoflora in the seed components when compare to the kharif 2008 season. This is due to the environmental factors like rainfall, temperature, humidity, P<sub>H</sub> and also in growth stages of the crop.

**Transmission studies in field**

The present study results revealed that the seeds having 19.2 % infection of *A. alternata* and 24.2% infection of *B. ricini* , showed the transmission of 16.6% in castor. (Average of five seed samples, table, 3).

**Recovery of the pathogen from seeds**

Seed samples were collected from the experimental plot were subjected for seed health testing methods for recovery of diseases transmission. The seeds collected from disease transmitted plants, sown in again during kharif season, infection having (30.8%) of *A. alternata* and *B. ricini* (32.6%) showed the (23.2%) transmission (Average of five seed samples, table, 4).

Reduction of the seed yield is based on the environmental conditions and the severity of disease symptoms. The mode of seed to seedling transmission of the pathogen is depends on the aggressiveness of the pathogen and environmental conditions. Current study revealed that the transmission of the pathogens were more during kharif 2008 than kharif 2007 harvested seeds. But disease transmission is more in kharif 2008 than kharif 2007 seasons. Mohit singh and shukla (1998) have reported the disease appeared in the first fortnight of July and gradually increased up to November, decline in disease severity with lowering the temperature and relative humidity up to December. Many researchers [2], [3], [5], [12], [17] have recorded the transmission of disease on different oil seed crops, like sesame, safflower, sunflower, soyabean, mustard, ground nut and chilli seeds etc. The present study reveals that the disease transmission is more during kharif-2008 than 2007 kharif season. The results shows that the kharif-2008 season favors more percentage of pathogens have transmission from the seed to seedling and to the seeds. Because this is environmental factors are influenced for the transmission of the pathogens.

**CONCLUSIONS**

*A. alternata* and *B. ricini* the causal agent of leaf spot, blight and gray mold disease of castor. Detection of Seed-borne *A. alternata* and *B. ricini* and other mycoflora plays an important role in determining the quality and longevity of seeds. Microbial invasion can lead to the rotting, loss of seed viability, germination, quality productivity and yield. It suggests that seeds are major agent of fungal transmission. Seeds should be treated with suitable chemical before sowing to reduce the fungal infection. This is due to the environmental factors like rainfall, humidity, temperature, P<sub>H</sub> and also in growth stages of the crop. Seed pathology involves the study of living entities, environmental factor affecting adversely to the seed production and utilization, as well as disease management practices applied to seed.

**ACKNOWLEDGEMENTS**

The authors are thankful to the Chairman, DOS in Applied Botany, Kuvempu University for providing facilities to carry out the present research work.
