ABSTRACT: In the present work we fabricated and compare of two different types of concrete (M35 Grade) samples, one is having steel fiber of 3% and another one has Metakaolin and steel fiber both. Experiment shows very good relation of mineral admixture and steel fiber with concrete strength against compressive force. We used different proportion of steel fiber and also mineral admixture and cured it at two different levels of 7 days and 28 days later, it increases its compressive strength, and also the requirement of cement is decreased with increase in proportion of fiber and mineral admixture. Prepared samples were tested for compressive strength on a machine having 2000 KN rated capacity. This experiment shows a great enhancement in compressive strength of concrete and is also shown graphically.

1. Introduction

Now a day’s human requirement is much higher than shelter, with the advancement of human societies, structure has to be more confined in space occupation, spacious and stronger than before. Modern structures are developed not only with pleasant appearance but also for long life and durability. Advance technology in civil engineering and in architecture helps designers and engineers to make a promise between appearance and strength. Apart from nature’s impact like in form of tycoons, flood and earthquake; structures also withstand in atmospheric condition like downpour, humidity and large variation in temperature according to climate. In the present work we also experimented with steel fibers and other ingredients (Metakaolin). Sample with different concentration and different size of fiber, were prepared and tested for the compressive strength against conventional concrete.

Data from the performed experiment were recorded and compressive strength related analysis have been done. Our main object of the work is to improve the compressive strength of the concrete without much changing in fabrication and casting process.

2. Materials

Locally available Ordinary Portland cement of grade 43 was used in the present work. The cement had a specific gravity of 3.15. Locally available dry aggregate was used in the concrete mixes. The maximum nominal size of the coarse aggregate was 20 mm and 10 mm, its specific gravity for coarse aggregates 20 mm size was 2.82 and coarse aggregates 10 mm specific gravity 2.90. The specific gravity of the fine aggregate (sand) was 2.65, and its fineness modulus was 2.57.

Steel fibers with Hooked end & Flat crimped were used in the mixes. The steel fibers had a length of 50 mm and a diameter of 0.75 mm (an aspect ratio of 100). The density of the fibers was 7.65 g/cm³ and the young’s modulus was 210 GPa.

Metakaolin (MK) is a reactive alumino-silicate pozzolan formed by burning purified kaolin or kaolinite clays at a specific temperature range and by grinding it to a high fineness. Metakaolin can be combined with calcium hydroxide to form hydrates. This contributes to improving properties of mortar and concrete. The reaction capacity of Metakaolin depends mainly on its mineral composition, on the raw kaolin source and on the conditions of production. Chemically, Metakaolin encompasses as main components oxides as SiO₂, Al₂O₃ and in smaller quantities the oxides Fe₂O₃, TiO₂, Na₂O and K₂O. The efficiency of metakaolin as a mineral admixture in cement and concrete is governed by high contents of SiO₂ and Al₂O₃.

The pozzolanic activity of Metakaolin is its ability to combine with calcium hydroxide to form cementitious compounds. This reactivity of the Metakaolin is predominantly governed by the type and amount of mineral compounds in the kaolin and by the calcination conditions.

The pozzolanic activity of commercial Metakaolin is in the range of 610-1150 (mg CaO/g), there by considerably exceeding the pozzolanic activity of silica fume 427 (mg CaO/g). Strength properties of paste and mortar are strongly influenced by kind, shape, size and spatial dispersion of hydrations products and by the pore characteristics. Partial replacement of Ordinary Portland Cement by Metakaolin was applied mid 1960s to improve the durability of concrete dams in Brazil. Since those days, the use of Metakaolin in cement and concrete has increased significantly. Metakaolin used in the cement and concrete industry. At present, Metakaolin is not only used in Ordinary Portland Cement and in normal concrete but also in high performance mortar and concrete.
Purified water that was clear and free of organic, chemical and physical impurities was used during the mixing and curing of the concrete specimens.

3. Sample Preparation
The mix proportion of 1: 1.77: 3.21 using I.S. Code 10262:2009 methods with water cement ratio 0.45 to different concrete mix by weight is determined to achieve the compressive characteristic strength of 35 N/mm², was considered for this work.

The exact quantity of materials for each mix was calculated using weigh batching. The parameters varied were percentage of fiber content.

The constituent of materials used for making the concrete were tested and the results are furnished in Table 1. The cement, fine aggregate, coarse aggregate steel fiber and Metakaolin were tested prior to the experiments and checked for conformity with relevant Indian standards.

4. Test Procedure
Designed are mixed by hand mixing on a clean cemented surface. To measure all ingredients i.e. cement, sand, coarse aggregates (20 mm and 10 mm), Steel fiber and Metakaolin we use weighed machine. The coarse aggregate (of 20mm and 10mm size), sand and cement and Metakaolin and steel fiber were mixed properly and mixing continued until uniformity was achieved by turning the mixture from one side to another side for many time until the color of the mixture is uniform. Assemble it all into a heap and make a hollow in the middle.

Add the water slowly into the hallow and mix in the material while turn the mixture again and again and make into a heap again, add more water and keep turning and mixture turned over again from side to side until it appeared uniform in color for about 3 minutes and we obtain the proper consistency after that material is filled into mould.

The standard tamping bar is also used for compacting the sample in the mould. The number of stroke of the bars is distributed in a uniform manner over the cross section of the mould. The number of stroke per layer required to produce the specified conditions is 35.

After Compaction by tamping bar vibration table was used to vibrate by means of an electric machine until the specific condition of minimum voids.

Moulds of dimension of 150mm×150mm×150mm was used for sample casting. After 24 hr, each specimen was removed from the mould and cured under water at 32±2°C until testing at age of 7 and 28 days. All specimens were cured in the same water tank to ensure uniform curing conditions.

The tests for measuring the compressive strength of the concrete specimens was carried out using Compressive Strength testing machine with a load at a constant rate within range per sec.

5. Cube Compressive Strength
Compressive strengths of the cubes (having steel fiber only) were tested for 7- days and 28- days and the test results are given Table 2. The maximum average compressive strength was 46.25 N/mm² at 28 days, obtained for a mix of fiber length of 50mm and fiber content of 3.0% by weight and the increase in strength over plain concrete was found to be 7%.

Compressive strengths of the cubes having both material Steel fiber and Metakaolin were tested for 7- days and 28- days and the test results are given Table.

**CONCLUSIONS**

The experiment shows that the effect of steel fiber can still be a promising work as there is always a need to overcome the problem of brittleness of concrete. The following conclusions could be drawn from the present investigation.

1. The maximum compressive strength of specimen after 28 days is 51.40 N/mm² with 3% of fibers and 10% of Metakaolin.

2. An increase of 11% in compressive strength is observed if 10% Metakaolin added with 3% of Steel fiber in to the mix as compare with only 3% of steel fiber.

3. An increase of 18% in compressive strength is observed if 10% Metakaolin added with 3% of Steel fiber in to the mix as compare with normal M-35 grade concrete without any additives.
