Abstract - It is shown, through two examples, that Rathore’s method for finding the minimal realization of a logic function of several variables is simpler and straight forward than Prasad’s method. The former has a distinct advantage of giving a complete set of minimal realizations at one stretch over the latter method.

Keywords: Boolean functions, Karnaugh map, Minimal realization, Prasad’s method, Rathore’s method

I. INTRODUCTION

There has been a lot of interest in minimizing a logic function to its minimal form [1-7]. Recently, Prasad [6] has proposed a method for reducing the logic function of many variables. Essentially, he obtains the minimal function in two major steps. In the first step, a complete set of all prime implicants is obtained, consisting of several sub-steps. Many K-maps of size 4x4 [8] are to be visualized. Many concepts, such as ‘prime implicants,’ ‘K-don’t cares,’ tree, leaf, parents, children, etc., are used. Therefore, it is quite lengthy and involved. In the second step, a minimal realization is obtained using some other method [9]-[12]. The author seems to be unaware of Rathore’s method (RM) [7] on similar work, as he does not refer to it. In the present work, a comparison of Prasad’s method (PM) and RM is given. It is shown that the latter method is straight-forward and simpler than the former one. This is shown by reducing two functions to their minimal forms. One function is given in the example, 2.1 of [6], and the other is taken from [7].

II. EXAMPLES

2.1 Example 1:

Find the minimal realization of the following function f_a , taken from [6], using RM [7].

$$\begin{aligned}
 f_a(x_1, x_2, x_3, x_4, x_5, x_6, x_7) &= x_1x_2x_3x_4 + x_4x_5x_6x_7 \\
 &+ x_2'x_3'x_4'x_5 + x_1x_4x_5x_7 + x_1'x_2x_4x_5'x_6' \\
 &= \left\{ \begin{array}{l} (4,5,6,7,15,31,40,41,47,56,57,63,68, \\ 69,70,71,77,79,93,95,109,111,120,121, \\ 122,123,124,125,126,127) \end{array} \right. \quad (1)
 \end{aligned}$$

To save space, only the first 32 minterms of f_a are shown in Fig.1 and its reduction process to arrive at f_{a1} . Remaining minterms are treated in a similar way to obtain f_{a2} , f_{a3} , f_{a4} . For convenience, a long table in the horizontal direction is divided into 2 Tables, as shown in Fig. 1(a) and 1(b). The final minimal function is shown as f in the last column of Fig. 1(b).

Elimination of LSB from one column to the next column is achieved using a truth table shown in Fig. 2 or relation in (2), or K-map of size 2x1 [8], repeatedly.

$$f = x'y + xz \quad (2)$$

Note that in each subsequent column, the number of rows is reduced by 50%. Only K-map of size 2x1 for 1 variable is used repeatedly. Note from (2), if $y = z = w$ then $f = w$. This reduces the number of literals. Hence, one must use this property wherever possible. The following Boolean identities may help to make $y = z$.

$$x + x' = 1 \quad (3)$$

$$1 = 1 + x \quad (4)$$

$$x + y = x y' + y = x + x'y \quad (5)$$

For example, in Fig. 1(a), each pair of two rows from top to bottom of column 2 is replaced using (2) in the next column. This eliminates the variable x_7 . Equation (5) may give additional minimal realizations.

If there are 2^n (n is an integer) entries in a block are 0 (1), then subsequent n columns will have all entries 0 (1). Such entries can be filled first in the entire table, then proceed to fill other entries as per the procedure suggested in [7] till only one row is left. This makes the method faster. For example, in Example 1, the entries corresponding to decimal numbers 0-3, 8-11, 16-19, 24-27 are 0, and 4-7 are filled in first. Thus, we need not handle all the minterms.

There are following two trivial cases where one would not like to go for the simplification method.

x	f
0	y
1	z

$f_{a4} = x_4x_5x_7 + x_3x_4$		

(b)

Fig. 1 Minimal realization of f_a using RM (a) First 7 columns and (b) remaining three columns

Case 1: A function has a single minterm. This itself is the simplified form.

Case 2: If there is an n variable function of two minterms such that all the literals are identical except the one which appears as compliments in the two min terms, then one can use the symmetry or repetition property [7] and get the simplification easily as any one of the minterms without this literal.

In RM, there exists an option to switch over to the 4x4 K map reduction process when 4 LSB are left. For example, 16 minterms are obtained from a column of $f_a(x_1x_2x_3x_4)$ for all the 128 minterms and filled in the 4x4 K map, as shown in Fig. 3. Now routine simplification will yield

$$f = x_1x_4x_5x_7 + x_4x_5x_6x_7 + x_1x_2x_3x_4 + x_2'x_3'x_4'x_5 + x_1'x_2x_4x_5'x_6'$$

which is the same as given in the last column of Table 1(b).

Fig. 3 K map for example 1

Prasad's revised method (PRM) [6] is used to eliminate some prime implicants obtained using the flowchart for getting minimal expression. This method proceeds through the following steps.

1. K -don't cares replaced with a single K .
2. A child node stops progressing if it doesn't have at least one minterm of value 1.

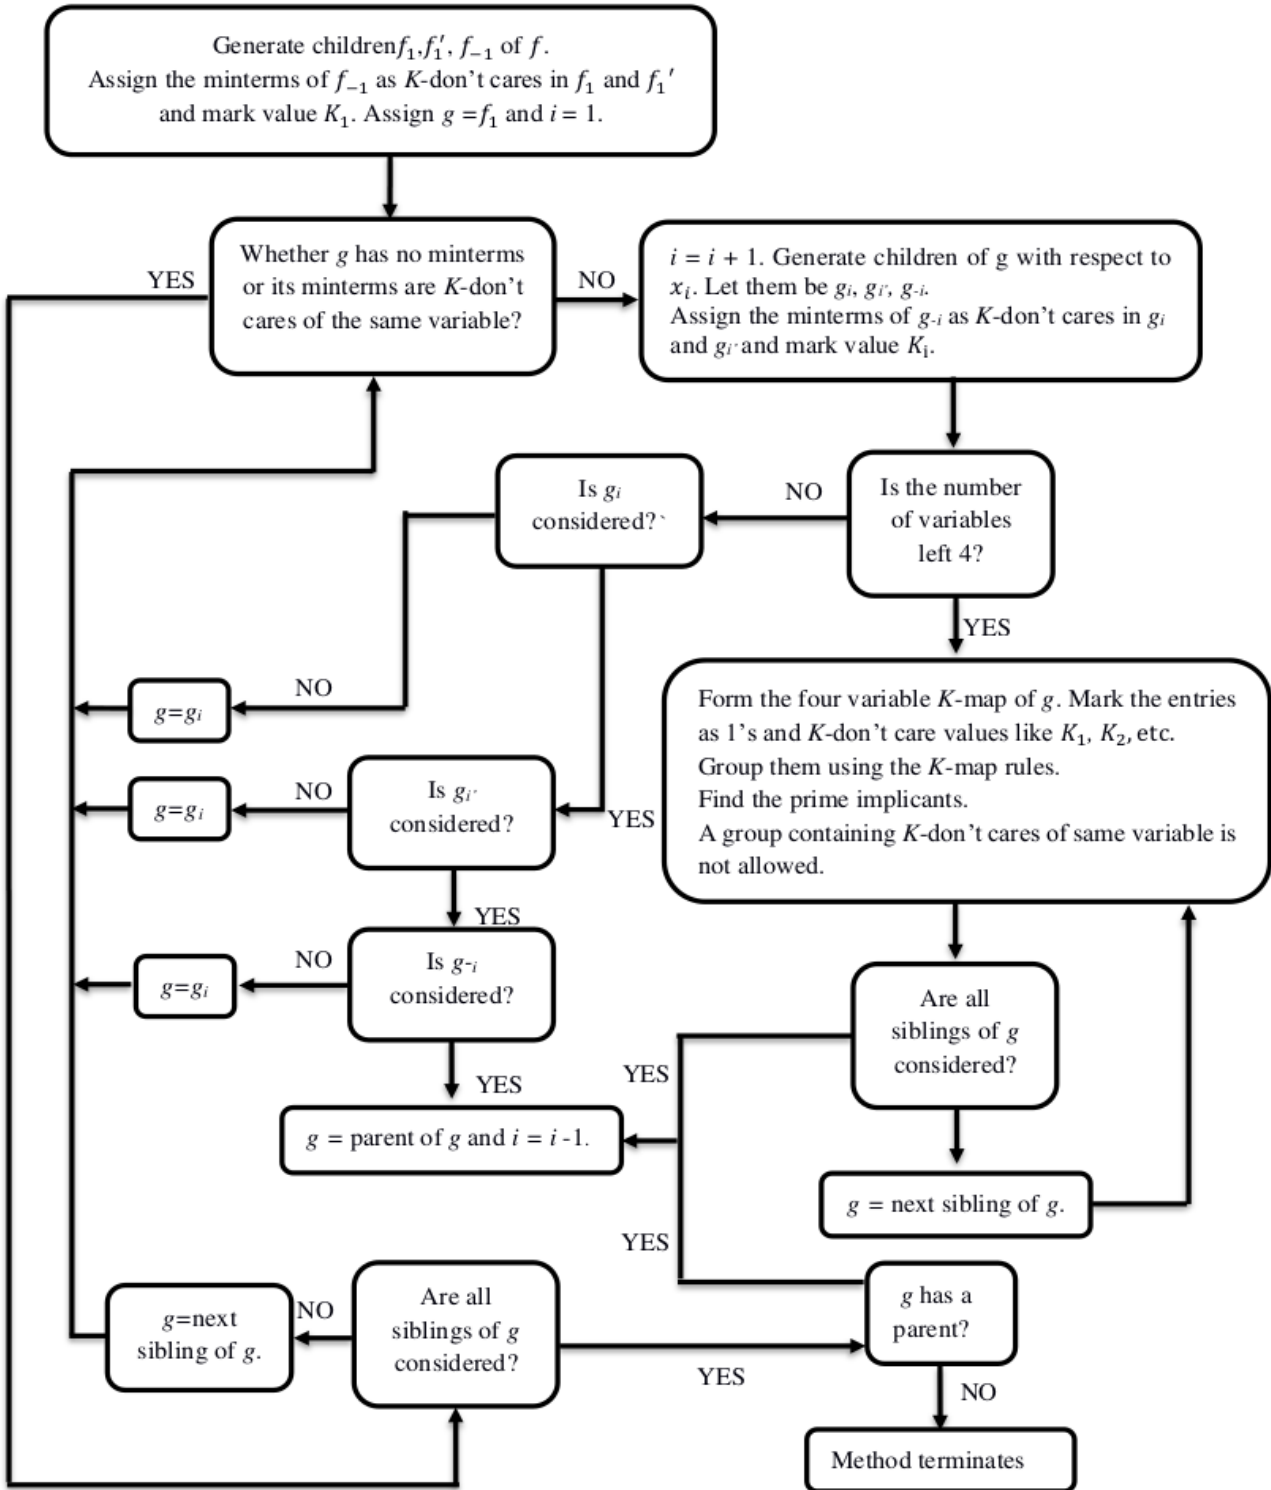

Fig. 4 A general flowchart for PM

3. While generating prime implicants, it should cover at least one 1 and a new 1 that is not present in other prime implicants generated so far.

2.2 Example 2:

Let the function to be minimized by

$$f_b = \sum (0,1,3,4,7,13,15,19,20,22,23,29,31) \quad (6)$$

The reduction of f_b using RM is given in Fig. 5. From Fig. 5(a), there have to be 9 possible outputs, but they all reduce to 4 only, as shown in Fig. 5(b). If the function given itself is minimal, the method gives all the minimal functions, including the one given. Thus, the RM provides an answer to the question: How many minimal realizations are possible for a given function, and what are they?

	f_b	$f_b(x_1x_2x_3x_4)$	$f_b(x_1x_2x_3)$	$f_b(x_1x_2)$	$f_b(x_1)$
0	1	1 + x_5	$x_5 + x_5'x_4'$ = x_4' + x_4x_5	$x_4'x_5' + x_4x_5 + x_3'x_5$ --- (i) OR $x_4'x_5' + x_4x_5 + x_3'x_4'$ --- (ii) = $x_3x_4'x_5' + x_4x_5 + x_3'x_4'$ ---(iii)	$x_2'x_4'x_5' + x_2'x_4x_5$ + $x_2'x_3'x_5 + x_2x_3x_5$ --- (a)

	Minimal Expressions for f_b
(a) & (d), (a) & (e)	$f_{b,min1} = x_2'x_4x_5 + x_2x_3x_5 + x_1'x_2'x_4'x_5' + x_1'x_2'x_3'x_5 + x_1x_2'x_3x_5'$
(b) & (d)	$f_{b,min2} = x_2'x_4x_5 + x_2x_3x_5 + x_1'x_2'x_4'x_5' + x_1'x_2'x_3'x_4' + x_1x_2'x_3x_5'$
(c) & (e), (b) & (e)	$f_{b,min3} = x_2'x_4x_5 + x_2x_3x_5 + x_2'x_3x_4'x_5' + x_1'x_2'x_3'x_4' + x_1x_2'x_3x_4$
(a) & (f), (b) & (f), (c) & (d), (c) & (f)	$f_{b,min4} = x_2'x_4x_5 + x_2x_3x_5 + x_2'x_3x_4'x_5' + x_1'x_2'x_3'x_4' + x_1x_2'x_3x_5'$

(b)

Fig. 5 Minimal realization of f_b using RM

Method	Number of variables	Number of the level of computations	Number of 4x4 K-map reductions	Remarks
PM	7	13	27	One additional step is required for PRM
RM		8	0	2x1 K-map reductions are considered in the number of level of computations
PM	5	1	3	Only one minimal expression is obtained after PRM
RM		6	0	All minimal expressions are obtained.

Fig. 6 Computational analysis of f_a and f_b using PM and RM.

Reduction of f_b using PM gives 8 prime implicants:

$$P_1 = x_2'x_4x_5, P_2 = x_2x_3x_5, P_3 = x_1'x_2'x_3'x_5, \\ P_4 = x_2'x_3x_4'x_5', P_5 = x_1'x_2'x_4'x_5', P_6 = x_1x_2'x_3x_5', \\ P_7 = x_1'x_2'x_3'x_4', P_8 = x_1x_2'x_3x_4.$$

It can be further reduced by eliminating P_3, P_5, P_6 since it doesn't group a new one that is not present in the prime implicants generated so far. Therefore, minimal expression of f_b can be written as

$$f_{b,min} = x_2'x_4x_5 + x_2x_3x_5 + x_2'x_3x_4'x_5' \\ + x_1'x_2'x_3'x_4' + x_1x_2'x_3x_4 \quad (7)$$

III. COMPARISON

1. In RM, all the product terms in the last column, such as in Fig. 1(b), are prime implicants and form a minimal function. Not a single extra prime implicant is generated. While in PM, all of the prime implicants are determined first and then Eliminate those which are in excess to form the minimal function.
2. Relations have been given by (3), (4), and (5), with which readers are already familiar, are used. So, one can easily adapt the method without involving any new concepts. While concepts such as 'prime implicants,' 'K-don't cares,' 'tree,' 'leaf,' 'parent nodes,' 'children,' 'grand-children,' etc. are involved in PM.
3. In PM, a K-map of size 4x4 is used, while in RM, a K-map of size 2x1 for 1 variable, as shown in Fig. 2, is used. Thus, it does not involve a higher K-maps size and, therefore, reduces the effort considerably.
4. In PM, all the prime implicants are found using the generalized K map method. Further, using PRM, some prime implicants are eliminated for getting one minimal function. In RM, the required prime implicants are automatically obtained and therefore no Need to reduce them to form minimal expression. Also, by writing $x + y$ in two possible ways ($x + x'y$ or $xy' + y$), we automatically get the complete set of all the minimal implicants as in Fig. 5 (b). While PM yields only one minimal expression given in (8).
5. The number of levels of computations required to solve an 'n' variable Boolean function in PM, obtained from the flow chart, is

$$N_L = 3^0 + 3^1 + 3^2 + 3^3 + \dots + 3^{n-5}$$

$$= \frac{3^{n-4} - 1}{2} \quad (7)$$

where $3^0, \dots, 3^{n-5}$ represent the number of sets of children that need to be considered at each level of the tree. The numeral '3' signifies the number of children for a parent. While RM requires only $(n+1)$ computational levels comprising 2x1 K-map simplifications. Thus, PM requires a larger N_L than RM for $n > 6$. Apart from this, in PM 3^{n-4} number of K-map of size 4x4 needs to be solved to find all the prime implicants. Computational analysis of f_a and f_b is given in Fig. 6.

IV. CONCLUSION

Through two examples, it is shown that RM for reducing a logic function of several variables to its minimal form is straight-forward and simpler than PM. Also, in the former method, a complete set of all the minimal expressions are found simultaneously. This is a distinct advantage of RM over PM.
