PHD candidate, Department of Economics and Management, Setif University, Setif, Algeria

Abstract**—** *The goal of this study is to investigate the relationship between oil price and the black market exchange rate US Dollar/Algerian Dinar through an empirical analysis using an ECM Model (Error Correction Model) upon quarterly data for the period 1975-2003. Results show that a cointegration relationship is detected between oil and black market exchange rate in Algeria, with unilateral trend causality in short and long run time horizon from oil prices to black market exchange rate*

Keywords **—** *oil price, Algerian black market exchange rate, EC Model.*

I. INTRODUCTION

Oil and gas revenues constitute the dominant income of the Algerian economy. This sector accounted, between "2002 – 2014", for 98% of exports, more than 40 % of GDP and 46 to 70 % of government revenue, see **Figure 1,** while trade openness, **see Table 1,** exhibits a high figure of 60% in the same period.

As far as the Algerian exchange rate is concerned, the central bank adopted, since 1996, a managed floating exchange rate after a long experience with the former regime (1974-1995)[1] that was built upon a strong concentration of the US dollar that played an important role due to its 98% in hydrocarbon export receipts. In Addition to that, the black market exchange rate US Dollar/Algerian Dinar is more than the official exchange rate about 45%. This importance gap between two exchange rates reveals the informal sector in the Algerian economy.

Between January 1975 and January 2003, the Algerian black market exchange rate has varied continuously; from January 1975 to January 1990, the black exchange rate appreciated quarterly about 28%, followed by another appreciation of 40% during the period 1990 tell 2003. Between January 1975 and January 2003, the Algerian dinar in black market depreciated against the U.S. dollar from 6 US/DZ to 82 US/DZ in the end period. Algerian exchange rate showed during these periods' remarkable depreciation with 3.85 US/DZ to 79US/DZ.

This contradictory situation between oil price and the black market exchange remains the main issue to be dealt with in this paper.

The goal of this study is to investigate the relathionship between the black market exchanges US Dollar/Algerian Dinar exchange rate and oil prices through an empirical analysis using an ECM Model (Error Correction Model) upon quarterly data for the period 1975-2003.

Literature Review

The oil price and the US dollar are the most attractive indices in the financial market. As the Algerian economy is highly vulnerable to oil price and US dollar fluctuations, we shall investigate, in this section, the dynamic relationship between oil price and exchange rates.

Firstly, Oil price plays a strategic role in the global economy. Many studies have highlighted its different impacts on macroeconomic variables such as GDP growth, unemployment rates, inflation, Stock market...(see: **Rasche, R. H. and J. A. Tatom (1977)** [1]**, Darby (1982)** [2] **Hamilton (1983**[3]**, 1996**[4]**, 2003**[5]**), Rotemberg and Woodford (1996)** [6]**, Eltony and Al-Awadi (2001)** [7]**, Brown and Yücel (2000)** [8]**, Blanchard and Gali (2007)** [9]**, Bjørland (2008)** [10]**.**

Secondly, the U.S. dollar is the most important currency in the world economy. It plays a major role in the pricing of oil and other commodities in the financial market. The domination of the US dollar in international trade as a currency commodity lets this currency serve as a central currency in the exchange rate arrangements of many countries in each area **(Linda S. G 2010)** [11]**.**

In the past years, particularly before 2002, oil price and US Dollar were moving in the same direction, when the US dollar rises, the price of oil is pushed up, and conversely, when the oil price increases, the US Dollar is appreciated. Since this period, the relationship between the two variables has changed because of the advent of many factors such as oil companies' targets, the role of the Euro currency, geopolitics, alternative sources of energy, speculators and Federal Reserve policy, and so forth…

[1] Algerian exchange rate was based upon a basket of 14 currencies.

In contrast, oil prices have risen while the dollar continued to weaken against other major currencies and the depreciation of the dollar could explain, therefore, the increase in oil prices. Since 2002, the price of a barrel of oil has increased fourfold, moving from $26 in 2002 to $107 in 2012. On the other hand, the U.S Dollar/Euro declined annually from 0.944 $US to $1.43 in 2010. Hence, many studies believe there are negative reverse causality between the U.S dollar and oil price during the last period (See, **Coull, 2009**[12], **Verleger (2008)** [13], **Setser (2008)** [14], **Virginie (2008)** [15]**).**

The study of **Chen and Rogoff (2003)** [16]detected a strong and stable influence of the US dollar price of non-energy commodity exports on the real exchange rates in two countries (Australia, New Zealand).. **Akram (2004)** [17], found out that there is a non–linear negative relationship between oil price and the Norwegian Krone over the sample between January 1986 and August 1998. Furthermore, this negative correlation varies along with the level and the trend in oil prices.

Koranchelian (2005) [18] finds that in the long-run, Algeria's real exchange rate is time varying, and depends on movements in relative productivity and real oil price. **Issa et al. (2006)** [19]pointed out in their study the depreciating effect of the energy price on the Canadian dollar before 1993 and the appreciation of the Canadian currency after this year. **Zalduendo (2006)** [20] used a vector error correction model to determine the impact of oil prices on the real equilibrium exchange rate in Venezuela. **Habib & Kalamova (2007)** [21] investigated whether the real oil price has an impact on the real exchange rates of three main oil-exporting countries: Russia (1995-2006), Norway and Saudi Arabia (1980-2006). In the first country, the authors found a positive long-run relationship between the real oil price and the real exchange rate. On the Contrary, for Norway and Saudi Arabia, results show that there is no impact between the two variables.

In Nigeria, many studies have used different types of empirical methods and examined the impact of oil price on exchange rate. While, **Olomola and Adejumo (2006)** [22] observed a positive impact where the oil price Shocks led to an exchange rate appreciation, **Iwayemi and Fawowe (2010)** [23] and **Adeniyi (2011)** [24] presented a negative relationship between oil price and exchange rate.

Korhonen et al. (2007) [25]estimated the real exchange rate in OPEC countries from 1975 to 2005 and three oil-producing Commonwealth Independent States (CIS) from1993 to 2005 using panel co-integration methods. Their results show that real oil price has a direct effect on the equilibrium exchange rate in oil-producing countries. **Nikbakht (2010)** [26] studied the long-run relationship between real oil prices and real exchange rates from 2000 to 2007 by using monthly panel of seven OPEC countries (Algeria, Indonesia, Iran, Kuwait, Nigeria, Saudi Arabia, and Venezuela). His result show there is a long-run and positive linkage between real oil prices and real exchange rates in the OPEC countries. **Chen and Chen (2007)** [27] carried out a similar analysis for G7 countries and they found a long run relationship between real oil prices and real exchange rates.

Colemanet all (2012) [28]found that shocks in the real price of oil are particularly important in determining the real exchange rates, even in the long run for a pool of African countries.

Beckmanna and Czudaj (2013) [29] pointed out in their study causality relationship between from effective dollar prices to oil prices through Markov-switching vector error correction model.

Nicolas Apergis (2014) [30] examined whether gold prices can be forecast the real and nominal Australian dollar exchange rate using daily and quarterly data via error correction model (ECM) during the period 2000-2012 , his results provided that gold price contain information about future development of the Australian dollar exchange rate.

Ferraro , Regoff and Rosi (2015) [31] investigated the existence of very short term relationship at the daily data between commodity prices and exchange rate, with their results indicated the out of sample forecasting have been appropriately taken into account.

III Model and Methodology

A. Data source

In our analysis, we make use of two macroeconomic variables: oil prices (oil) and the black market exchange US dollar/Algerian Dinar (US/DZ). The sample comprises 113 quarterly observations for the period 1975 - 2003.The sources of oil prices are collected from US. Energy information administration (eia),while, data on black market exchange rate are collected from global financial data.

B. Definition of the ECM Model

In this case, non-stationary and bilateral co integrated series, the error correction (ECM) would be best to use in this case and for forecasting systems of interrelated time series and for analyzing the dynamic impact of random disturbances on the system of variables.

The mathematical representation of a VECM is:

$$\Delta y_{1,t} = a_1 (y_{2,t-1} - b y_{1,t-1}) + e_{1,t}$$

$$\Delta y_{2,t} = a_2 (y_{2,t} - 1 - b_{y1,t-1}) + e_{2,t}$$

Where y_1 and y_2 deviate from the long run equilibrium, the error correction term will be nonzero and each variable adjusts to partially restore the equilibrium relation. The coefficient measures the

speed of adjustment of the *i*-th endogenous variable towards the equilibrium.

IV Results and Comment

Before presenting the results from the empirical EC Model see **Okonkwo (2015)** [32], we shall be applying the following econometric steps:

- ✓ Test the stationary of the time series data by Augmented Dickey-Fuller& Philips and Perron.
- ✓ Analysis co-integration tests
- ✓ Causality test.
- ✓ Error correction model

A. Stationarity tests

Most classical econometric estimations as least square method (GLS) based on non-stationary time series produce spurious regression and statistics may simply indicate only correlated trends rather than a true relationship **(Granger and Newbold, 1974)** [33]. Augmented **Dickey-Fuller (1979, 1981)** [34] and **Philips and Perron, (1988)** [35] tests can help avoid false results through stationary test of times series**.** Our results drawn from stationary tests represented in tables (2) and (3) allow a rejection of the null hypothesis in first difference that signify no stationarity in all our series, but enable an acceptation at a level, that signify integration of the variables at order 1.

Table 2: Stationary test results

Variables	ADF		PP	
	Level	First difference	Level	First difference
oil	-2.70	-4.39	-2.23	-8.25
bex	-0 90	–9.50	- 0.71	-9.50
Test critical values	-2.88 at 5%			

B. Analysis of co-integration tests

In order to explain the relationship between oil price and the Algerian exchange rate in long run, **Engle and Granger (1981, 1987)** [36, 37], in their paper, estimated cointegration of non-stationary time-series variables for demonstrating the existence of cointegration between two macroeconomic variables implies "a true long-run economic relationship" which prevents the residuals

The results of the Signal-equation co-integration test indicate that there is one minimum short run relationship between black market exchange rate of Algerian and oil price (no cointegration at the 0.05 level, (**see Tables 3**).

Table 3: Cointegration test

Dependent	tau-statistic	Prob.*	z-statistic	Prob.*
oil	-1.20	0. 91	-2.35	0.0241
Bex	-2.78	0.03	-21.04	0.9685
*MacKinnon (1996) p-values.				

4-Granger causality

In this case, we use Granger causality tests of Clive Granger (1969) for determining whether oil prices is useful in causing the Algerian exchange rate with lagged values of two variables included. Granger causality test reported in table 4 made it clear that one directional flow at 5% significance level for oil prices to Algerian black market exchange rate. This relationship can be clarified how the Algerian Dinar is depend on oil prices change to the effect that the foreign exchange receipts from hydrocarbon exports.

Table 4: Granger causality

Pairwise Granger Causality Tests		
Lags: 2		
NullHypothesis:	F-Statistic	Prob.
Bex does not Granger Cause oil	4. 77	0.04
oil does not Granger Cause bex	0.73	0.39

V. Conclusion

In this paper, we investigated if the oil price in US dollar and black market exchange rate have a cointegrated relationship in the run long. Our results show that there is a cointegrated relationship. In the case of Algeria, The main conclusion is that the Algerian exchange rate can be explained by fundamentals complemented with oil price. In fact, high prices of oil generally provoke a large appreciation of exchange rates in oil-exporting countries, but this evidence is clearly established in the Algerian case, evidenced over the last four decades with the existence of a co-integration relationship between the Algerian black market exchange rate and oil price.
